Submitted by: ISTA-PDC Method Validation Sub-committee

Background
This method was originally published in the ISTA Handbook of Seed Health Testing in 1981 as Working Sheet No. 44 prepared by C. Anselme and R. Champion, La Minière, France. The method appears in annex 7.4.3.A.2 of the ISTA Rules (1999). It has been incorporated into the new Annexe to Chapter 7, Seed Health Testing Methods as method 7-003 and is subject to review before 2006.
Safety Precautions
Ensure you are familiar with hazard data and take appropriate safety precautions, especially during preparation of media, autoclaving and weighing out of ingredients. It is assumed that this procedure is being carried out in microbiological laboratory by persons familiar with the principles of Good Laboratory Practice, Good Microbiological Practice, and aseptic technique. Dispose of all waste materials in an appropriate way (e.g. autoclave, disinfect) and in accordance with local safety regulations.

Treated seed
This method may be influenced by treatment applied to the seed lot. Seed health tests on chemically treated seeds will generally deliver unreliable test results caused by masking or inhibition of the growth of the target organism.

Materials

<table>
<thead>
<tr>
<th>Reference Material</th>
<th>- The use of reference cultures or other appropriate material is recommended whenever possible.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Media</td>
<td>- Blotters (Whatman No 1) 3% malt solution</td>
</tr>
<tr>
<td>Petri dishes</td>
<td>- When sowing density is given by a number of seeds per petri dish, a diameter of 90 mm is assumed.</td>
</tr>
<tr>
<td>Incubator</td>
<td>- Capable of operating in the range 20°C ± 2°C.</td>
</tr>
</tbody>
</table>

Sample Preparation
The test is carried out on a working sample of 400 seeds as described in Section 7.4.1 of the ISTA Rules.

Method
1. Pretreatment
   None.
2. Blotter
   Place two pieces (88 mm in diameter) of filter paper (Whatman No.1) in each of 80, 90 mm diameter Petri dish, and add 5 ml of a solution of 3% malt extract. Pour off the excess liquid and plant 5 seeds in each petri dish.
3. Incubation
   9 days at 20°C in darkness.
4. Examination
   After 5, 7 and 9 days examine the seeds by naked eye for roots showing a soft rot and covered by an abundant grey mycelium (Fig. 1). These seeds are recorded as infected. Examination is repeated after 7 and 9 days incubation. New infections are marked on the blotter, and the sum of the three counts gives the total infection.
In doubtful cases confirmation may be made by examining the mycelium at x200 magnification for septae, ribbon-like hyphae and tufts of branching conidiophores (Fig. 3).

**General Methods (common to many test procedures)**

1. **Checking tolerances**
   Tolerances provide a means of assessing whether or not the variation in result within or between tests is sufficiently wide as to raise doubts about the accuracy of the results. A tolerance table, which can be applied to most direct seed health tests, can be found in Table 5.1 of Annex 15 of the ISTA Rules or in Table G1 of the Handbook of Tolerances and Measures of Precision for Seed Testing by S. R. Miles (Proceedings of the International Seed Testing Association 28 (1963) No 3, pp 644).

2. **Reporting Results**
   The result of a seed health test should indicate the scientific name of the pathogen detected and the percentage of infected seeds. When reported on an ISTA Certificate results are entered under Other Determinations. The results should be accompanied by information on the test method used, including any pretreatment.

**Quality Assurance**

**Critical Control Points**

None Listed
